

Robust Regression with Particle Swarm Optimisation and Differential Evolution

Enrico Schumann
enricoschumann@yahoo.de

1 Introduction

We provide a code example for a robust regression problem. The purpose of this vignette is to provide the code in a convenient way; for more details, please see Gilli et al. [2011]. (The vignette builds on the script `comparisonLMS.R`.)

2 Data and settings

We start by attaching the package.

```
> require("NMOF")
> require("MASS")
> set.seed(11223344)
```

We will use the function `lqs` from the `MASS` package [Venables and Ripley, 2002]. We will use an artificial data set with n observations and p regressors, created with the function `createData`.

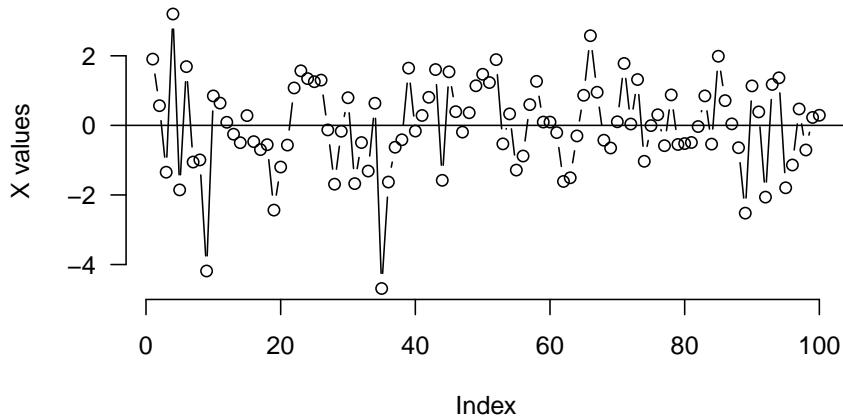

```
> createData <- function(n, p, constant = TRUE,
+                         sigma = 2, oFrac = 0.1) {
+   X <- array(rnorm(n * p), dim = c(n, p))
+   if (constant) X[, 1L] <- 1L
+   b <- rnorm(p)
+   y <- X %*% b + rnorm(n)*0.5
+   n0 <- ceiling(oFrac*n)
+   when <- sample.int(n, n0)
+   X[when, -1L] <- X[when, -1L] + rnorm(n0, sd = sigma)
+   list(X = X, y = y)
+ }
```

We start by creating some artificial data. We collect X and y in the list `data`. We also add the scalar h which gives the order statistic of the squared residuals to be minimised. Note that we put `as.vector(y)` into `data` so that the vector gets ‘recycled’ in the objective function.

```
> n <- 100L    ### number of observations
> p <- 10L    ### number of regressors
> constant <- TRUE; sigma <- 3; oFrac <- 0.1
> h <- 75L    ### ... or use something like floor((n+1)/2)
> aux <- createData(n, p, constant, sigma, oFrac)
> X <- aux$X; y <- aux$y
> data <- list(y = as.vector(y), X = X, h = h)
```

The outliers are visible.

```
> par(bty = "n", las = 1)
> plot(X[, 2L], type = "b", ylab = "X values")
> abline(h = 0)
```

Two example objective functions, Least Trimmed Squares (LTS) and Least Quantile of Squares (LQS). Note that they are almost identical.

```
> OF <- function(param, data) {
+   X <- data$X; y <- data$y
+   aux <- y - X %*% param
+   aux <- aux * aux
+   aux <- apply(aux, 2L, sort, partial = data$h)
+   colSums(aux[1:data$h, ]) #### LTS
+ }
> OF <- function(param, data) {
+   X <- data$X; y <- data$y
+   aux <- y - X %*% param
+   aux <- aux * aux
+   aux <- apply(aux, 2L, sort, partial = data$h)
+   aux[data$h, ] #### LQS
+ }
```

Both functions are vectorised. They work with a single solution (`param` would be a vector) or a whole population (`param` would be a matrix; each column would be one solution).

3 Using DE and PSO

We run DE and PSO. We compare the result with `lqs`.

```
> popsize <- 100L; generations <- 500L
> ps <- list(min = rep(-10,p),
+             max = rep( 10,p),
+             c1 = 0.5,
+             c2 = 1.1,
+             iner = 0.9,
+             initV = 1,
+             nP = popsize,
+             nG = generations,
+             maxV = 5,
+             loopOF = FALSE,
+             printBar = FALSE,
+             printDetail = FALSE)
> de <- list(min = rep(-10,p),
+             max = rep( 10,p),
+             nP = popsize,
```

```

+           nG = generations,
+           F = 0.7,
+           CR = 0.9,
+           loopOF = FALSE,
+           printBar = FALSE,
+           printDetail = FALSE)
> system.time(solPS <- PSopt(OF = OF, algo = ps, data = data))

  user  system elapsed
 3.124   0.004   3.125

> system.time(solDE <- DEopt(OF = OF, algo = de, data = data))

  user  system elapsed
 3.052   0.000   3.051

> if (require(MASS, quietly = TRUE)) {
+   system.time(test1 <- lqs(y ~ X[, -1L],
+                             adjust = TRUE,
+                             nsamp = 100000L,
+                             method = "lqs",
+                             quantile = h))
+   res1 <- sort((y - X %*% as.matrix(coef(test1)))^2)[h]
+ } else res1 <- NA
> (res2 <- sort((y - X %*% as.matrix(solPS$xbest))^2)[h])

[1] 0.2633539

> (res3 <- sort((y - X %*% as.matrix(solDE$xbest))^2)[h])

[1] 0.2798945

> cat("lqs: ", res1, "\n",
+      "PSopt: ", res2, "\n",
+      "DEopt: ", res3, "\n", sep = "")

lqs:  0.3807335
PSopt: 0.2633539
DEopt: 0.2798945

```

To demonstrate the advantage of a vectorised objective function, we can compare it with looping over the solutions. We first set `loopOF` to TRUE, so we actually loop over the solutions. (We also reduce the number of objective function evaluations.)

```

> popsize <- 20L; generations <- 150L
> de$nP <- popsize; de$nG <- generations
> ps$nP <- popsize; ps$nG <- generations
> de$loopOF <- TRUE; ps$loopOF <- TRUE
> (t1ps <- system.time(solPS <- PSopt(OF = OF, algo = ps, data = data)))

  user  system elapsed
 0.544   0.004   0.548

> (t1de <- system.time(solDE <- DEopt(OF = OF, algo = de, data = data)))

  user  system elapsed
 0.532   0.000   0.533

```

To evaluate the objective function in one step, we `loopOF` to FALSE.

```

> de$loopOF <- FALSE; ps$loopOF <- FALSE
> (t2ps <- system.time(solPS <- PSopt(OF = OF, algo = ps, data = data)))

```

```

user  system elapsed
0.212    0.000   0.213

> (t2de <- system.time(solDE <- DEopt(OF = OF, algo = de, data = data)))

user  system elapsed
0.204    0.000   0.203

```

Speedup:

```

> t1ps[[3L]]/t2ps[[3L]]
[1] 2.57277
> t1de[[3L]]/t2de[[3L]]
[1] 2.625616

```
